#### Abstract

We study the class $\mathcal{L}$ of link types that admit a $K_{4}$-minor-free diagram, i.e., they can be projected on the plane so that the resulting graph does not contain any subdivision of $K_{4}$. We prove that $\mathcal{L}$ is the closure of a subclass of torus links under the operation of connected sum. Using this structural result, we enumerate $\mathcal{L}$ and subclasses of it, with respect to the minimal number of crossings or edges in a projection of $L \in \mathcal{L}$. Further, we enumerate (both exactly and asymptotically) all connected $K_{4}$-minor-free link diagrams, all minimal connected $K_{4}$-minor-free link diagrams, and all $K_{4}$-minor-free diagrams of the unknot.

Keywords: series-parallel graphs, links, knots, generating functions, asymptotic enumeration, map enumeration

## 1 Introduction

The exhaustive generation of knots and links is a well-established problem in low dimensional geometry (see [7, Ch.5], for instance). However, there are very few enumerative results in the literature and they are relatively recent, (see [10] and [6]). Moreover, there seems to be no known results connecting graph theoretic classes with link classes.

Let us start with some formal definitions. A knot $K$ is a smooth embedding of the 1-dimensional sphere $\mathbb{S}^{1}$ in $\mathbb{R}^{3}$. A link is a finite disjoint union of knots $L=K_{1} \cup \ldots \cup K_{n}$. Two links $L_{1}$ and $L_{2}$ are equivalent if there is a continuous and injective function $h: \mathbb{R}^{3} \times[0,1] \rightarrow \mathbb{R}^{3}$, such that $h\left(L_{1}, 0\right)=L_{1}$ and $h\left(L_{1}, 1\right)=L_{2}$. A link equivalent to a set of non intertwined circles is called a trivial link. If it is a knot, we also call it the unknot.

Consider a link $L$ and a sphere $\mathbb{S}^{2}$ embedded in such a way that it meets the link transversely in exactly two points $P_{1}$ and $P_{2}$. Then we can discern two different links $L_{1}, L_{2}$, after connecting $P_{1}$ and $P_{2}$. The first corresponds to the part of $L$ in the interior of the sphere and the second to the part in the exterior. We then call $L$ a connected sum with factors $L_{1}, L_{2}$, denoted $L_{1} \# L_{2}$. A link that does not have non-trivial factors is called prime, otherwise composite. A link is split if there is a sphere embedded in the link complement that separates the link. Each of the components is called a disjoint component of the link and, conversely, the link is their disjoint sum.

Let $L \in \mathbb{R}^{3}$ be a link and let $\pi: \mathbb{R}^{3} \rightarrow \mathbb{R}^{2}$ be a projection map. If for all $x \in L,\left|\pi^{-1}(x)\right|=2$ or 1 , and all the double points are finite and transverse, then the projection is said to be regular. For all knots defined here, there exists a regular projection [2, Ch. 3]. This allows to work with link-diagrams, i.e. a triple $(V, E, \sigma)$, where $(V, E)$ is a 4-regular plane graph and $\sigma: V(G) \rightarrow\binom{E(G)}{2}$, where, for every $v \in V(G), \sigma(v)$ is a set of two opposite edges of the embedding of $G$ and encodes which pair is overcrossing. Notice that a link-diagram may also have vertexless edges. We call these edges trivial. The crossing number of a link $L$ is the minimum number of crossings that can have a diagram of it. Such a diagram is called minimal. We also say that a diagram $(V, E, \sigma)$ is $K_{4}$-minor-free if the graph $(V, E)$ does not contain

[^0]any subgraph that is a subdivision of a $K_{4}$.
A torus link is a link that can be embedded on the torus. They are denoted by $T(p, q), p, q \in \mathbb{Z}$, where $p$ and $q$ are the number of times that the link crosses the meridian and the longitude cycle, respectively. Let $\mathcal{T}_{2}$ be the closure of torus links of type $T(2, q), q \in \mathbb{Z}-\{0\}$, under the connected sum operation. Let $\mathcal{L}$ be the class of links that have a $K_{4}$-minor-free link-diagram and $\operatorname{mcl}\left(\mathcal{T}_{2}\right)$ be the closure of $\mathcal{T}_{2}$ under disjoint sum.

## 2 Structure of $K_{4}$-links and enumeration

Our first result gives the type of links that admit a $K_{4}$-minor-free diagram.
Theorem 2.1 The links that admit a $K_{4}$-minor-free diagram are exactly the ones in $\operatorname{mcl}\left(\mathcal{T}_{2}\right)$, i.e. $\mathcal{L}=\operatorname{mcl}\left(\mathcal{T}_{2}\right)$.

Based on the above, we derive a precise description of links that admit a $K_{4}$-minor-free diagram. Let $\overline{\mathcal{L}}$ be the class of non-split links in $\mathcal{L}$ and $\hat{\mathcal{L}}$ the class of links in $\mathcal{L}$ with no trivial disjoint components, with size defined as their crossing number. We will obtain the asymptotic growth of $\mathcal{L}$ with respect to the number of edges in a minimal diagram (not the crossing number, so as to account also for trivial disjoint components). Let $L(z), \bar{L}(z)$, and $\hat{L}(z)$ be the respective generating functions. Finally, let $\mathcal{T}$ be the class of non plane, unrooted trees, where the vertices are labelled with multisets of the set $\{1\} \cup\{ \pm 3, \pm 5, \ldots\}$ and the edges are labelled with an element of the set $\{2, \pm 4, \pm 6, \ldots\}$. These labels will encode crossing numbers, hence a label $i$ corresponds to size $|i|$. The size of $T \in \mathcal{T}$ is the sum of its labels. See Figure 1 for an example of such a tree.

Figure 1. An object of $\mathcal{T}$.

Proposition $2.2 \overline{\mathcal{L}} \cong \mathcal{T}$ and $\operatorname{MSet}_{\geq 1}\left(\mathcal{T} \backslash T_{1}\right) \cong \hat{\mathcal{L}}$, where MSet is the multiset operator with at least one element and $T_{1} \in \mathcal{T}$ is the tree with one vertex and label 1.

Using Proposition 2.2 and the framework of the Symbolic Method (see [4]), we derive combinatorial expressions for $\mathcal{L}$ that translate to generating functions. Let $\overline{\mathcal{K}}$ and $\mathcal{K}$ be the classes of prime knots and composite knots plus the trivial knot in $\mathcal{L}$, respectively. For prime knots in $\mathcal{L}$, i.e. prime torus knots $T(2,2 i+1), i \in \mathbb{Z} \backslash\{0,-1\}$, it holds that $\bar{K}(z)=2 \sum_{i \geq 1} z^{2 i+1}=\frac{2 z^{3}}{1-z^{2}}$, counting according to their crossing number. For $\mathcal{K}$, it is enough to consider non-empty multisets of prime torus knots, therefore $\mathcal{K}=\operatorname{MSet}_{\geq 1}(\overline{\mathcal{K}})$, which translates to the expression

$$
K(z)=\exp \left(\sum_{k \geq 1} \frac{1}{k} \bar{K}\left(z^{k}\right)\right)-1=\exp \left(\sum_{k \geq 1} \frac{1}{k} \frac{2 z^{3 k}}{1-z^{2 k}}\right)-1 .
$$

Let $\mathcal{G}$ be the class of unrooted and unlabelled non-plane trees. Notice that one cannot replace immediately $z$ for $\mathcal{K}$ in the ogf $G(z)$, since the vertices are not distinguishable. Hence, to continue, one needs to use cycle indices. Let $\mathcal{G} \cdot$ be the class of rooted and unlabelled non-plane trees. For the cycle index of $\mathcal{G}^{\bullet}$, it is known (see [1]) that

$$
\mathcal{Z}_{\mathcal{G}} \bullet\left(s_{1}, s_{2}, \ldots\right)=s_{1} \exp \left(\sum_{k \geq 1} \frac{1}{k} \mathcal{Z}_{\mathcal{G}}\left(s_{k}, s_{2 k}, \ldots\right)\right)
$$

Let $\mathcal{E}$ be the combinatorial class of the edge labels of $\mathcal{T}$, hence $E(z)=z^{2}+\frac{2 z^{4}}{1-z^{2}}$, and let $f(z)=E(z) K(z)$. We can now obtain the ordinary generating function of $\mathcal{F}=\mathcal{T}^{\bullet} \circ\left(\mathcal{E} \times \mathcal{L}_{c}\right)$. By Polya's Theorem, the latter satisfies the equation $F(z)=\mathcal{Z}_{\mathcal{G}} \cdot\left(f(z), f\left(z^{2}\right), \ldots\right)$. Then, it holds that

$$
\bar{L}(z)=\frac{F(z)}{E(z)}+\frac{E(z)}{2}\left(-\frac{F(z)^{2}}{E(z)^{2}}+\frac{F\left(z^{2}\right)}{E\left(z^{2}\right)}\right),
$$

by the Dissymmetry Theorem (see [1]). The first terms of $\bar{L}(z)$ are as follows:

$$
\bar{L}=1+z^{2}+2 z^{3}+3 z^{4}+4 z^{5}+9 z^{6}+12 z^{7}+26 z^{8}+40 z^{9}+\ldots
$$

We can then get asymptotic estimates by means of complex analytic tools:
Theorem 2.3 $\overline{\mathcal{L}}$ has asymptotic growth of the form:

$$
\left[z^{n}\right] \bar{L}(z) \sim \frac{c n^{-3 / 2}}{\Gamma(-1 / 2)} \rho^{-n}, \quad \rho \approx 0.44074, \quad c \approx 1.45557
$$

Additionally, $\hat{\mathcal{L}}$ has the same type of asymptotic growth with the same $\rho$ and $c \approx 3.61691$.

The generating function $L(z)$ is equal to $\hat{L}\left(z^{2}\right) \frac{1}{1-z}$, since a link diagram of $n$ vertices has $2 n$ non-trivial edges and a number of trivial edges. We thus obtain the following corollary.

Corollary $2.4 \mathcal{L}$ has asymptotic growth of the form:

$$
\left[z^{n}\right] L(z) \sim \frac{c n^{-3 / 2}}{\Gamma(-1 / 2)} \rho^{-n}
$$

where $\rho \approx 0.44074$ and $c \approx 8.97779$ or $c \approx 3.95687$, depending on whether $n$ is even or odd, respectively.

Finally, we also get asymptotic estimates for the coefficients of $K(z)$. The following result is a consequence of Meinardus' Theorem (see [4, VIII.23]).

Theorem 2.5 $\mathcal{K}$ has asymptotic growth of the form:

$$
\left[z^{n}\right] K(z) \sim c n^{-7 / 4} \exp \left(c^{\prime} n^{1 / 2}\right)
$$

where $c=\frac{\mathrm{e}^{2 \ln (2) \zeta(0)}(\Gamma(2) \zeta(2))^{5 / 4}}{2 \sqrt{\pi}} \approx 0.26275, c^{\prime}=2 \sqrt{\Gamma(2) \zeta(2)} \approx 2.56509$, and $\zeta(z)$ is the Riemann zeta function.

## 3 Enumeration of families of link diagrams

Enumerating connected $K_{4}$-free link-diagrams is equivalent to enumerating 4-regular unrooted planar maps which are $K_{4}$-minor-free, that we call $\overline{\mathcal{M}}_{1}$. We first give a construction for the rooted ones, $\mathcal{M}_{1}$, with respect to edges, adapting the construction for rooted 4 -regular maps in [8]. With this we obtain a functional system of equations that can be analyzed by using the analytic machinery developed by Drmota in [3]. Finally, by adapting an argument by Richmond and Wormald in [9], we are able to show that we can unroot the maps under study, showing that the maps in our class with non-trivial automorphisms are exponentially few. This study gives the following result:

Theorem 3.1 The class of connected $K_{4}$-free link diagrams $\overline{\mathcal{M}}_{1}$ satisfies that

$$
\left[z^{n}\right] \bar{M}_{1}(z) \sim \frac{1}{2 n} \frac{c n^{-3 / 2}}{\Gamma(-1 / 2)} \rho^{-n} 2^{n}, \rho \approx 0.31184, c \approx 1.52265
$$

Refining the combinatoric analysis in the previous case (with more auxiliary classes) and using again an adaptation of the argument of Richmond and Wormald in [9], we are able to asymptotically enumerate also the class of minimal link diagrams $\overline{\mathcal{M}}_{2}$, as well as the class of $K_{4}$-free link diagrams of the unknot, $\overline{\mathcal{M}}_{3}$ :

Theorem 3.2 The class of connected $K_{4}$-free minimal link diagrams $\overline{\mathcal{M}}_{2}$, and
the class of $K_{4}$-free link diagrams of the unknot, $\overline{\mathcal{M}}_{3}$ satisfy:

$$
\begin{aligned}
& {\left[z^{n}\right] \bar{M}_{2}(z) \sim \frac{1}{2 n} \frac{c_{2} n^{-3 / 2}}{\Gamma(-1 / 2)} \rho_{2}^{-n}, \rho_{2} \approx 0.41456, c_{2} \approx 0.81415,} \\
& {\left[z^{n}\right] \bar{M}_{3}(z) \sim \frac{1}{2 n} \frac{c_{3} n^{-3 / 2}}{\Gamma(-1 / 2)} \rho_{3}^{-n}, \rho_{3} \approx 0.23188, c_{3} \approx 2.19020}
\end{aligned}
$$
